

Collaborative Discussion 1: Structural Design Patterns

Adapter Pattern

In the first scenario, I implemented the Adapter Pattern for cyber security log monitoring. I created a LogAdapter to connect a legacy log collector with a modern monitoring system.

The adapter converts the legacy string-based logs into the standard format used by the `get_events()` interface. This allows both legacy and modern events to be processed in the same way without modifying the legacy component.

```
from abc import ABC, abstractmethod

# Target Interface
class SecurityEventSource(ABC):

    @abstractmethod
    def get_events(self):
        pass

# Legacy System
class LegacyLogCollector:

    def read_old_logs(self):
        return [
            "LOGIN_FAIL|10.10.1.10",
            "MALWARE_ALERT|DC-01",
            "MALWARE_ALERT|server-05"
        ]

# LogAdapter:
class LogAdapter(SecurityEventSource):

    def __init__(self, legacy_collector):
        # store the legacy system in the adapter
        self.legacy_collector = legacy_collector

    def get_events(self):
```

```

        events = []
        legacy_logs = self.legacy_collector.read_old_logs()

        for log in legacy_logs:
            event_type, source = log.split("|")

            # convert it into the new format
            events.append({
                "event": event_type,
                "source": source,
                "system": "Legacy System"
            })
        return events

#Modern System
class ModernLogCollector(SecurityEventSource):
    def get_events(self):
        return [
            {
                "event": "BRUTE_FORCE",
                "source": "192.168.1.20",
                "system": "Modern System"
            },
            {
                "event": "SUSPICIOUS_LOGIN",
                "source": "WEB-SERVER-01",
                "system": "Modern System"
            }
        ]

# create the log sources
legacy_source = LogAdapter(LegacyLogCollector())
modern_source = ModernLogCollector()
sources = [
    legacy_source,
    modern_source
]

# merge logs from the legacy and modern systems
all_events = []
for source in sources:
    all_events.extend(source.get_events())

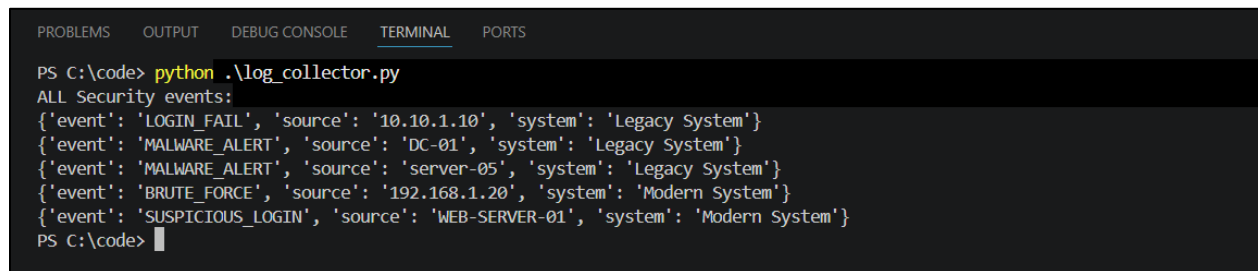

# display the combined security events

```

```
print("ALL Security events:")
for event in all_events:
    print(event)
```

The result:

The legacy logs were successfully adapted and processed with the modern security events.

A screenshot of a terminal window with a dark background. At the top, there are tabs labeled 'PROBLEMS', 'OUTPUT', 'DEBUG CONSOLE', 'TERMINAL' (which is selected), and 'PORTS'. The terminal shows a PowerShell prompt 'PS C:\code>' followed by the command 'python .\log_collector.py'. The output of the script is displayed below the command, starting with 'ALL Security events:' followed by five JSON objects representing security events. The events include details like event type (e.g., LOGIN_FAIL, MALWARE_ALERT), source IP or identifier, and the system type (Legacy System or Modern System). The prompt 'PS C:\code>' is visible again at the bottom of the terminal.

```
PS C:\code> python .\log_collector.py
ALL Security events:
{'event': 'LOGIN_FAIL', 'source': '10.10.1.10', 'system': 'Legacy System'}
{'event': 'MALWARE_ALERT', 'source': 'DC-01', 'system': 'Legacy System'}
{'event': 'MALWARE_ALERT', 'source': 'server-05', 'system': 'Legacy System'}
{'event': 'BRUTE_FORCE', 'source': '192.168.1.20', 'system': 'Modern System'}
{'event': 'SUSPICIOUS_LOGIN', 'source': 'WEB-SERVER-01', 'system': 'Modern System'}
PS C:\code>
```

Bridge Pattern

In the second scenario, I applied the Bridge Pattern to a cyber security alert system. The alert types are separated from the delivery channels using the AlertChannel interface.

SecurityAlert uses the selected channel to deliver the message, while CriticalAlert adds a critical priority label. This allows alerts to use different delivery channels without creating a separate class for each combination.

```
from abc import ABC, abstractmethod
class AlertChannel(ABC):

    @abstractmethod
    def send(self, message):
        pass
# Sends the alert to the console
class ConsoleChannel(AlertChannel):

    def send(self, message):
```

```

        print(f"Console: {message}")

# Sends the alert through SMS
class SMSChannel(AlertChannel):

    def send(self, message):
        print(f"SMS: {message}")

# Sends the alert through email
class EmailChannel(AlertChannel):

    def send(self, message):
        print(f"Email: {message}")

# -- Bridge:
# The alert does not know how the message is delivered It only uses the
AlertChannel interface.

class SecurityAlert:

    def __init__(self, channel):
        # Store the selected delivery channel
        self.channel = channel

    def notify(self, message):
        # Delegate the delivery to the channel
        self.channel.send(message)

# Critical Alert extends Security Alert and changes the alert behaviour without
changing the delivery channel.
class CriticalAlert(SecurityAlert):

    def notify(self, message):
        self.channel.send(f"CRITICAL - {message}")

#-- The alert type and the delivery channel can be combined independently.
# Normal security alert sent to the console
SecurityAlert(ConsoleChannel()).notify(
    "New login detected"
)

# Critical security alert sent through email

```

```

CriticalAlert(EmailChannel()).notify(
    "Malware detected"
)

# Critical security alert sent through SMS
CriticalAlert(SMSChannel()).notify(
    "Malware detected"
)

```

The result:

Security alerts were delivered through different channels using the same alert structure.

```

PS C:\code> python .\security_alerts.py
Console: New login detected
Email: CRITICAL - Malware detected
SMS: CRITICAL - Malware detected
PS C:\code>

```

Composite Pattern

In the third scenario, I applied the Composite Pattern to a network asset inventory. The AssetComponent interface allows both individual devices and groups of devices to use the same show() method.

Device represents a single asset, while AssetGroup can contain devices or other groups. This allows network assets to be organised and displayed as a hierarchical structure through the same interface.

```

from abc import ABC, abstractmethod

#interface
class AssetComponent(ABC):

```

```

    @abstractmethod
    def show(self, indent=0):
        pass

# network device
class Device(AssetComponent):

    def __init__(self, name):
        self.name = name

    def show(self, indent=0):
        print(" " * indent + self.name)

# Composite Devices or AssetGroups
class AssetGroup(AssetComponent):

    def __init__(self, name):
        self.name = name
        self.children = []

    def add(self, component):
        self.children.append(component)

    def show(self, indent=0):
        print(" " * indent + self.name)

        for child in self.children:
            child.show(indent + 2)

# create network asset

firewall_01 = Device("Firewall-01")
firewall_02 = Device("Firewall-02")

web_server = Device("Web-Server-01")

database_01 = Device("Database-Server-01")
database_02 = Device("Database-Server-02")

security_workstation_01 = Device("Security-Analyst-Workstation-01")
security_workstation_02 = Device("Security-Analyst-Workstation-02")
security_workstation_03 = Device("Security-Analyst-Workstation-03")

employee_workstation_01 = Device("Employee-Workstation-01")

```

```
employee_workstation_02 = Device("Employee-Workstation-02")
employee_workstation_03 = Device("Employee-Workstation-03")
employee_workstation_04 = Device("Employee-Workstation-04")

#-- Create asset groups

# Firewall group
security_perimeter = AssetGroup("Security Perimeter")
security_perimeter.add(firewall_01)
security_perimeter.add(firewall_02)

# Server group
server_network = AssetGroup("Server Network")
server_network.add(web_server)
server_network.add(database_01)
server_network.add(database_02)

# Security team workstation group
security_team = AssetGroup("Security Team")
security_team.add(security_workstation_01)
security_team.add(security_workstation_02)
security_team.add(security_workstation_03)

# Normal employee workstation group
employee_network = AssetGroup("Employee Network")
employee_network.add(employee_workstation_01)
employee_network.add(employee_workstation_02)
employee_network.add(employee_workstation_03)
employee_network.add(employee_workstation_04)

# Main Composite
# Office Network contains several different asset groups

office_network = AssetGroup("Office Network")

office_network.add(security_perimeter)
office_network.add(server_network)
office_network.add(security_team)
office_network.add(employee_network)

# Display the complete network Asset
```

```
office_network.show()
```

The result:

Individual devices and asset groups were displayed as one hierarchical network structure.

The screenshot shows a terminal window with a dark background. At the top, there are tabs for 'PROBLEMS', 'OUTPUT', 'DEBUG CONSOLE', 'TERMINAL' (which is selected), and 'PORTS'. The terminal content shows a PowerShell prompt 'PS C:\code>' followed by the command 'python .\network_asset_inventory.py'. The output is a hierarchical list of network assets: 'Office Network' (indented), 'Security Perimeter' (indented), 'Firewall-01' and 'Firewall-02' (further indented), 'Server Network' (indented), 'Web-Server-01', 'Database-Server-01', and 'Database-Server-02' (further indented), 'Security Team' (indented), 'Security-Analyst-Workstation-01', 'Security-Analyst-Workstation-02', and 'Security-Analyst-Workstation-03' (further indented), 'Employee Network' (indented), and 'Employee-Workstation-01', 'Employee-Workstation-02', 'Employee-Workstation-03', and 'Employee-Workstation-04' (further indented). The prompt 'PS C:\code>' is visible at the bottom.

```
PS C:\code> python .\network_asset_inventory.py
Office Network
  Security Perimeter
    Firewall-01
    Firewall-02
  Server Network
    Web-Server-01
    Database-Server-01
    Database-Server-02
  Security Team
    Security-Analyst-Workstation-01
    Security-Analyst-Workstation-02
    Security-Analyst-Workstation-03
  Employee Network
    Employee-Workstation-01
    Employee-Workstation-02
    Employee-Workstation-03
    Employee-Workstation-04
PS C:\code>
```
